摘 要	
Keywords have been widely applied to conversation searching system in instant messaging; however, people may not remember specific contents, which means this keyword-centered design may be infeasible and causes difficulties during searching. Therefore, this study focuses on finding out attributes for users to recall instant messaging conversations and providing recommendations for designers to design tools helping users retrieve conversation more effectively. An experiment was conducted with 29 participants. They were asked to chat with others through instant messaging and take recall tasks one week later. The results of the recall task indicated what kind of attributes could be recalled more easily and design implication were also discussed.
